

Business Intelligence Overview Report

1. Definition of Business Intelligence

Business Intelligence (BI) is a group of processes and software tools. BI collects, stores, cleans, and analyzes company data. This technology changes raw data into clear information. Companies use BI to make correct decisions from facts. BI removes the need to make business decisions from feelings or guesses.

2. Purpose of Dashboards

Companies make a large amount of transactional data every day. This data comes from many regions, customer segments, and products. Raw databases and spreadsheets are difficult to read quickly. Companies use interactive dashboards to collect this data into one visual screen. Dashboards use automated processes to calculate values. They show the differences between high performance and operational problems.

3. How Dashboards Improve Decisions

Interactive dashboards help managers see data clearly. improving decisions through these capabilities:

- **Immediate Monitoring:** Managers see key performance indicators quickly with high-level summaries.
- **Detailed Analysis:** Filters let users click on a region or a year.
- **Data Selection:** Users can find the root cause of a financial change immediately.
- **Trend Analysis:** Line charts show sales data over time.
- **Planning:** Charts help managers predict customer demand and control inventory.
- **Risk Control:** Dashboards show low-profit areas quickly to protect company money.

4. Project Objective and Dataset

This project uses the **Superstore Sales Dataset** to analyze a retail company. The objective is to change raw retail data into an interactive Power BI dashboard for managers. The dashboard answers questions about revenue, regional profit, customer segments, and product performance. This report gives data-driven recommendations to increase profit and optimize distribution logistics.
